The **OPERA** (Optical Spectroscopy of Nanostructured Materials) group coordinated by the candidate boasts a long-standing, internationally acknowledged expertise on the electronic properties of nanostructured semiconductor materials, either spontaneously formed or artificially created. The scientific activities of OPERA rely on optical spectroscopy techniques based on photoluminescence (PL) and its variants (PL excitation, PL under magnetic field and hydrostatic pressure, time-resolved-PL), Raman scattering, reflectance, second-harmonic generation, and second order photon-correlation techniques. Post-growth hydrogen irradiation is also employed as a powerful tool to fine tune the material electronic properties that

has led to important discoveries, such as the passivation of nitrogen impurities in III-V alloys and the creation of spatially controlled strain fields in two-dimensional materials. An important asset of the activities of OPERA concerns the use of high magnetic fields that has provided the group with important international recognitions.

The candidate is deputy-coordinator of **SMART** (Spectro-Microscopy lAboRaTory), a departmental laboratory established thanks to the “Departments of Excellence 2018-2022” funding scheme of the Ministry of University and Research. The laboratory is open to external users on proposal-based applications. SMART is meant to address several scientific and technological challenges related to novel materials of use in diverse contexts. These comprise nanostructures for quantum and green technologies and flexible electronics; dielectric coatings of mirrors in interferometers employed for gravitational wave detection; detectors for high-energy physics and dark matter; superconductors. The scientific approach of SMART is holistic in character and lies on the possibility to perform treatments and functionalisation by hydrogen and alkali metals of the sample surfaces and nanostructures and to study them with integrated spectroscopic techniques within the same ultra-high-vacuum environment ( $10^{-11}$  mbar). At SMART, micro-PL and micro Raman spectroscopy with few hundred-nanometre spatial resolution, and X-Ray Photoelectron Spectroscopy (XPS) with tens of micron spatial resolution can be carried out within the same contaminant-free environment before and after in-situ treatments.

## Part VI – Research highlights

The candidate coordinates the group of “Optical Spectroscopy of Nanostructured Materials” (OPERA) at the Physics Department, Sapienza Università di Roma (<https://antoniopolimeni-physics.weebly.com/>).

He is also Deputy Coordinator of the Departmental Laboratory **Spectro-Microscopy IAbRaTory** (SMART) at the Physics Department, Sapienza Università di Roma

(<https://sites.google.com/uniroma1.it/smартlab>) founded as “Department of Excellence” 2018-2022 by the Ministry of Research and University. The laboratory is open to external users on proposal-based applications.

He is co-PI within Spoke 4 of the **National Quantum Science and Technology Institute**.

The research activity of the candidate revolves around the fascinating field of nanostructured materials and the engineered modulation of their electronic properties. The candidate's interests have encompassed the study of various systems, including inorganic semiconductors in the bulk and reduced-dimensionality form (quantum wells, quantum wires, quantum dots and nanowires) and the exploitation of self-assembled quantum dots as active medium in laser devices and tunnelling devices. Two-dimensional materials obtained from van der Waals crystals concern the most recent activity of the candidate. The electronic, optical, vibrational, transport and spin properties of those systems are addressed by optical spectroscopy techniques also under the presence of high magnetic fields (30 T) and hydrostatic pressure (10 kbar). A hallmark of the main scientific achievements of the candidate concerns the effects of low-energy (10-100 eV) hydrogen-ion irradiation on various materials. In particular, the candidate demonstrated the possibility to control spatially the incorporation of hydrogen as to modify controllably the material characteristics down to the nanometer scale. This has enabled the fabrication of site-controlled quantum emitters, and the observation of strain-driven intriguing quantum mechanical effects, such as exciton level hybridisation.

During his scientific activity, the candidate set-up various optical spectroscopy, optoelectronic (for laser characterisation) and transport apparatuses including superconducting magnets both in UK and Rome. He implemented cryogenics systems with diffraction-limited photoluminescence and Raman set-ups. He is expert in both continuous-wave and time-resolved photoluminescence measurements, as well as second harmonic generation spectroscopy and second-order correlation measurements for quantum light characterisation. Noticeably, he developed the use of a Kaufman source for low-energy (10-500 eV) light-ion (H, He) irradiation of many semiconductor materials. The candidate coordinated a project for the integration of a similar Kaufman in the SMART laboratory permitting the treatment of samples and subsequent studies by micro-electronic/optical spectroscopies within the same contaminant-free environment.

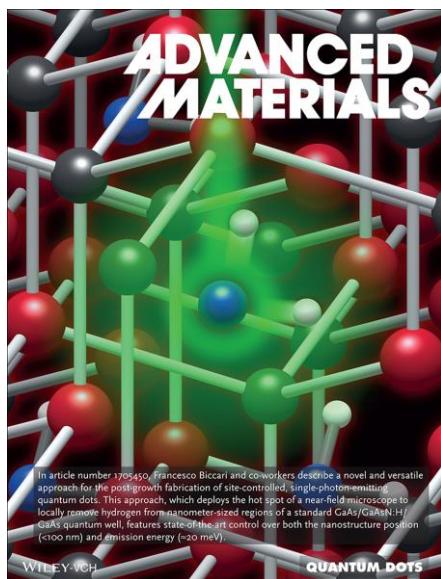

### Semiconductor nanostructures and devices

During the PhD in Physics (1993-1996), the activity of the candidate concerned the effects of compositional and morphological disorder on the **optical properties of semiconductor quantum wells [8] and quantum dots [12]**.

In the group of “*Quantum Transport and Spectroscopy of Semiconductors*” at the University of Nottingham, from 1997 to 1999, as a Research Assistant, he investigated the **transport [19], structural [18], and magneto-optical properties of quantum dots [27] and their application as active medium in lasers [18,31] and quantum tunnelling devices [51,52]**.

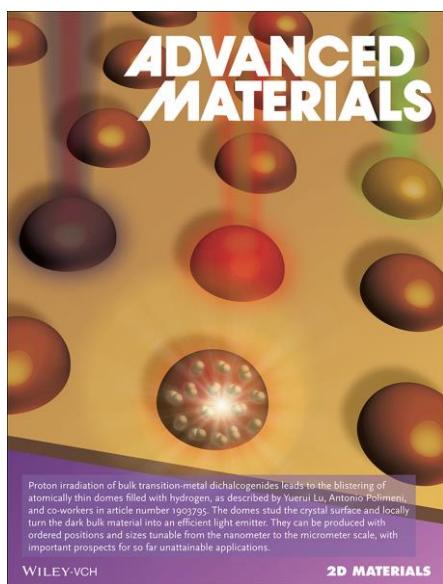

### Semiconductor nanostructuring by hydrogen irradiation

In Rome, as Researcher (since 2000) and Associate Professor (since 2010), the candidate **discovered the hydrogen-induced passivation of nitrogen atoms in dilute nitrides. He conceived and pioneered the hydrogen-assisted fabrication of novel nanostructures [63,112,149,200]** with planar architecture that paved the way to the recent realization of site-controlled single photon sources embedded in photonic structures [200], as depicted in the next picture.

The use of hydrogen has become an asset of the group coordinated by candidate. In 2019, he **pioneered the strain engineering of the electronic and mechanical properties of two-dimensional materials by hydrogen irradiation** aimed at quantum technology applications [210]. In particular, the candidate and his group observed that the low-energy hydrogen-ion irradiation of van der Waals crystals (*e.g.*, transition metal dichalcogenides and hexagonal boron nitride) leads to the formation of hydrogen-filled, nanometer/micrometer-sized, spherical bubbles made of a single monolayer directly lifted from the underlying lattice, as highlighted in the next figure. Owing to the membrane curvature and hydrogen internal pressure of tens to hundreds of atm, the atomically thin membranes experience unprecedently high strain values (up to about 10%) [216] that has led to a plethora of interesting phenomena [244,243,239,237,232,] and provided a tool for addressing the mechanical properties of those materials [227].

Very recently, the candidate collaborated with other groups for the use of low-energy irradiation for energy storage applications [251] (see next figure), thus witnessing the breath of interest of this technique in various materials and applicative fields.

### Magneto-optical spectroscopy applied to low-dimensional systems

A significant part of the candidate's activity regarded the exploitation of **high magnetic fields to address the spin and transport properties of various material systems comprising** dilute nitride III-V semiconductors [86,108,116,120] and **III-V nanowires** [196]. The latter are filamentary crystals with unique crystal phase properties that reflects on the exciton magnetic moment and effective mass, as the candidate showed in the studies he performed and coordinated [208,207,197,191,179,172].

Recently, he **unveiled strain-induced hybridisation effects on the electronic properties of two-dimensional crystals** by high-field Zeeman-splitting measurements of the exciton magnetic moment in mechanically deformed membranes [239], as reported below.

- [https://emfl.eu/emflwebsite/wp-content/uploads/2022/11/emfl\\_newsletter\\_n3\\_22\\_web.pdf](https://emfl.eu/emflwebsite/wp-content/uploads/2022/11/emfl_newsletter_n3_22_web.pdf)

The candidate further revealed how magnetic fields are a tool of uttermost importance to understand the properties of novel 2D systems consisting in twisted-bilayer-heterostructures. In these systems, a **moiré effect** is created, leading to the trapping of carriers in the moiré potential minima. The candidate research is highlighting how **moiré-trapped excitons feature peculiar characteristics that differ from those of excitons in 2D materials**, making them of interest for quantum applications or for collective phenomena [249].

In addition to III-V, III-nitride-V, II-VI semiconductors and two-dimensional materials, the candidate investigated also the optical properties of perovskites [198,226,230,238,242] and nano-porous graphene [221,235,246].
